Chilean Miners Rescue Plan

Chilean rescuers spent 40 days drilling a borehole in an effort to save the Chilean miners trapped under the earth at the depth of 700 meters since August 5

San Jose Mine

Phoenix rescue capsule

Three capsules have been designed specially for the operation

The shaft has special belts to monitor the blood pressure, temperature, pulse and breathing rate

Oxygen system

Communication system

Safety belts

First borehole (which provides ventilation of the shaft and supplies to the miners)

Stages of rescue operation

- 1 Drilling a borehole with a pneumatic hammer that throws the earth to the surface
- 2 Increasing the diameter size of the borehole to 66 centimeters (26 inches) with the use of a bar with a cutter
- 3 Descent of two volunteers (mine specialist and military doctor) to test the capsule
- 4 Pulling up the miners one by one to the surface in the rescue capsule

After reaching the surface:

- miners will be given dark glasses to protect their eyes from bright sunlight
- miners will undergo a medical examination
- miners will be delivered to a field hospital installed near the mine
- once the condition of the rescued miners stabilize, they will be transferred to a medical center in Copiapo in the Atacama Region
